

EOT Event Log Compiler — Product Specification

InfraMind EPC | Product Concept Note | June 2026

Prepared by Samanta Nayak — Manager, Contracts & Claims | Infrastructure AI Architect

What It Is

EOT Event Log Compiler is a proposed tool concept for structuring delay events and supporting records into a usable Extension of Time event log. It is intended to help project teams capture chronology earlier, reduce retrospective reconstruction, and improve the quality of EOT preparation.

The concept is rooted in a practical reality: on most projects, events happen in sequence, but records accumulate in fragments. By the time a claim is prepared, teams often spend excessive effort reconstructing what should have been tracked as events unfolded.

The Problem It Solves

Delay claims become weak when chronology is rebuilt too late. Correspondence sits in one place, programme updates in another, and site records in yet another. Without a structured event log, the team loses time trying to connect cause, date, impact, and contractual significance.

That leads to:

- incomplete event histories,
- weak cause-and-effect presentation,
- slower EOT preparation,
- avoidable dependence on retrospective reconstruction.

EOT Event Log Compiler is intended to improve that transition from raw records to claim-ready event structure.

Proposed Use Cases

- extension of time event registers

- delay chronology building
- event-to-record mapping
- contemporaneous record structuring for claims
- internal preparation before formal EOT submission
- support input for delay analysis and claim narrative drafting

Core Functional Intent

Capability	Purpose
Event capture structure	Helps organise event date, description, source, and impact
Record linkage	Connects event entries to available supporting references
Chronology building	Presents events in a usable time sequence
EOT support preparation	Improves readiness for formal delay analysis and EOT claims
Review-ready log output	Produces a structured log for project, claims, or legal review

Intended Output Logic

A useful event log should do more than list dates. It should help a reviewer understand what happened, when it happened, what record supports it, and why it matters to entitlement.

A typical output structure may include:

- event date,
- event title,
- factual description,
- source record reference,
- affected activity or workfront,
- potential delay relevance,
- remarks / review note.

Positioning

This is a product concept, not a currently marketed deployed software platform. It is being shaped as a practical claims-support tool based on recurring pain points in delay and EOT preparation on EPC projects.

Its purpose is to improve record discipline and claim readiness, while leaving final analysis and claim strategy with the responsible professionals.

Who It Is For

- Contracts and Claims Managers
- Delay Analysts
- Planning Engineers
- Project Controls teams
- Commercial teams compiling EOT submissions
- Legal and expert support teams reviewing chronology

Why It Is Different

Generic trackers record issues. They do not necessarily structure events the way an EOT claim needs them. EOT Event Log Compiler is intended to bridge that gap by focusing on chronology, source traceability, and claim usefulness.

The emphasis is not on dashboard complexity. It is on getting the event record into a form that can actually support entitlement analysis.

Current Status

Status: Product concept / specification stage

No live client deployment is being claimed at this stage. The concept is part of the InfraMind EPC product direction and may be further developed through prototype or pilot refinement.
